

SELECTED SOLUTIONS FOR COMPUTABILITY 2019

RUIZHI YANG

- Exercise 4.2.9.** (1) Show that every infinite, finitely branching tree T has a path recursive in T'' .
 (2) Build a recursive tree containing at least one path and every path of it computes $0''$.

Proof. (1) Given an infinite, finitely branching tree T . We define a $\Delta_3^0(T)$ path P so that $P \leq_T T''$. Let

$$P = \{ \sigma \in \mathbb{N}^{<\mathbb{N}} \mid \exists f \in (\mathbb{N}^{<\mathbb{N}})^{|\sigma|+1} (\varphi(f) \wedge f(|\sigma|) = \sigma) \},$$

Note that $f \in (\mathbb{N}^{<\mathbb{N}})^{|\sigma|+1}$ means $f : |\sigma| + 1 \rightarrow \mathbb{N}^{<\mathbb{N}}$, so it is a $|\sigma| + 1$ long sequence of finite sequence of natural numbers. Note also that $\exists f \in (\mathbb{N}^{<\mathbb{N}})^{|\sigma|+1}$ is not a bounded quantifier. We would expect $\varphi(f)$ saying that f is a sequence telling us how to inductively choose an infinite path. Explicitly, $\varphi(f)$ can be written as

$$f(0) = \langle \rangle \wedge \forall n + 1 \in \text{dom } f \exists k \in \text{ran}(\text{ran } f)(f(n+1) = f(n) \frown \langle k \rangle \wedge \psi(k, f, n)).$$

where $\psi(k, f, n)$ roughly says that k is the *least* choice so that the subtree above $f(n) \frown \langle k \rangle$ is still an infinite tree. More explicitly, $\psi(k, f, n)$ is

$$\begin{aligned} & \forall \exists \tau \in \mathbb{N}^l (\tau \in T \wedge \tau \upharpoonright (n+2) = f(n+1)) \\ & \wedge \forall k' < k (f(n) \frown \langle k' \rangle \in T \rightarrow \exists \forall \tau \in \mathbb{N}^l (\tau \in T \rightarrow \tau \upharpoonright (n+2) \neq f(n) \frown \langle k' \rangle)). \end{aligned}$$

Note that the quantifiers in red are unbounded. Therefore P can be defined by a $\Sigma_3^0(T)$ formula. Since it can be proved that such a sequence f is unique, P can also be defined as

$$P = \{ \sigma \in \mathbb{N}^{<\mathbb{N}} \mid \forall f \in (\mathbb{N}^{<\mathbb{N}})^{|\sigma|+1} (\varphi(f) \rightarrow f(|\sigma|) = \sigma) \}.$$

In this case P is also $\Pi_3^0(T)$, hence $\Delta_3^0(T)$

This a proof of (2) given by Liu Yong.

IDEA:

We want to construct a tree containing at least one path and whose every path P satisfying.

$$(4.2.9.1) \quad P(e) = \begin{cases} \text{the starting stage for } P \upharpoonright e, & \text{if } \Phi_e^{0'}(e) \uparrow, \\ t \text{ (>the starting stage for } P \upharpoonright e), & \text{if } \Phi_e^{0'}(e) \downarrow. \end{cases}$$

The *starting stage* for $P \upharpoonright e$ is a number $s \geq e$ serving two purposes. First, it indicates that eventually $\Phi_e^{0'}(e) \uparrow$; second, if for some $d < e$, $P(d)$ is landing at its own starting stage claiming that Φ_d will diverge, then s is informative (big) enough to see an evidence that it is right to make that claim.

CONSTRUCTION: First, we define $s_\sigma \in \mathbb{N}$ being the starting stage for $\sigma \in \mathbb{N}^{<\mathbb{N}}$ inductively as follow: Assume $|\sigma| = e$, s_σ is the *starting stage* for σ if and only if

s_σ is the least $\geq e$ such that for every $d < e$, if $\sigma(d)$ is the starting stage (indicating that Φ_d will diverge), then there is $t \in [e, s_\sigma]$ witnessing that $\Phi_{d,t}^{0'_t}(d) \uparrow$. Note that $\{\langle \sigma, s \mid s \text{ is the starting stage for } \sigma \rangle\}$ is recursive.

Now, fix $\sigma \in \mathbb{N}^{<\mathbb{N}}$ such that $|\sigma| = e$, and $s \in \mathbb{N}$. Assume inductively that we know $\sigma \in T$. We want to see if $\sigma \hat{\ } s \in T$.

(a) If there is $d < e$ such that $\sigma(d) >$ the starting stage for $\sigma \upharpoonright d$, $\Phi_{d,\sigma(d)}^{0'_{\sigma(d)}}(d) \downarrow$, and $e > \sigma(d)$ is the least such that $\Phi_{d,e}^{0'_e}(d) \uparrow$, then $\sigma \hat{\ } s \notin T$. Note that this decision is made regardless of s . The idea is that we exam to the step e , as soon as we find some previous converged Φ_d diverges, we stop any extension recording a $< e$ down stage for level d .

(b) $\sigma \hat{\ } s \in T$ only if s is either the starting stage for σ or a down stage $>$ the starting stage. Note that if there is some $d < e$ such that $\sigma(d)$ is the starting stage while we cannot find a witness of diverge in $[e, s_\sigma]$, then $\sigma \hat{\ } s \notin T$.

This completes the construction of T .

VERIFICATION:

- (i) T is a recursive tree by construction.
- (ii) Let P be such that

$$P(e) = \begin{cases} \text{the starting stage for } P \upharpoonright e, & \text{if } \Phi_e^{0'_e}(e) \uparrow, \\ t, & \text{if } t > \text{the starting stage for } P \upharpoonright e, \\ & \Phi_{e,t}^{0'_t}(e) \downarrow \text{ and } 0'_t \upharpoonright (\text{use } \Phi_{e,t}^{0'_t}(e)) \prec 0'. \end{cases}$$

Then P will be a path on T . Note first that such a path won't be killed by (a). The starting stages are all well defined, namely cannot be infinite. Finally, show that it won't be killed because of (b) in any cases.

(iii) Any path P on T must satisfies (4.2.9.1). By (b), $P(e)$ can only be the starting stage for $P \upharpoonright e$, or a down stage.

Assume to a contradiction that $\Phi_e^{0'_e}(e) \downarrow$ while $P(e)$ is the starting stage for $P \upharpoonright e$. Then for some $t > e$, $\Phi_{e,t}^{0'_t}(e)$ will stay at converge afterwards, and for any $d \geq t$, we can find no witness for the claiming of divergence, no starting stage for $P \upharpoonright d$ (or the starting stage being ∞), and so no extension of $P \upharpoonright d$ in T .

Now, assume $P(e) = t$ is a down stage, namely $\Phi_{e,t}^{0'_t}(e) \downarrow$. If eventually $\Phi_e^{0'_e}(e) \uparrow$, then it will be killed by (a) at some stage.

- (iv) $0'' \leq_T P$. To see if $e \in 0''$, check if $P(e)$ is the starting stage for $P \upharpoonright e$.

This another proof of (2) given by Wang Sa.

IDEA:

Recall that we can construct a finitely branching recursive tree T^0 containing a unique path $P \equiv_T 0'$. By relativization, we can construct a finitely branching tree $T^A \leq_T A$ containing a unique path $P \equiv_T A'$. For a string $\sigma \prec A$, we can compute a finite subtree T^σ of an initial segment of T^A by making sure the use of A not exceeding $|\sigma|$.

We construct a infinite branching recursive tree T^* so that its even levels recording the construction of T^0 , while the odd levels using a node σ of T^0 to compute an finite subtree of an initial segment of T^σ and a cofinal path of T^σ .

In the end, the even part of a path of T^* would be the path P of T^0 and $P \equiv_T 0'$; the odd part of T^* recording the construction of a path of T^P , which computes $P' \equiv_T 0''$.

CONSTRUCTION:

By induction, we assume $\rho \in T^*$ and try to decide if a successor of ρ is in T^* .

If $|\rho|$ is even. We put $\rho \frown \{\sigma\}$ into T^* , only if $\sigma \in T^0$ and for any even $i < |\rho|$, $\rho(i) \prec \sigma$.

If $|\rho| = 2e + 1$ is odd. We use $\sigma = \rho(e)$ as oracle. We put $\rho \frown \{\langle t, p \rangle\}$ into T^* , only if it satisfies

- (a) t is a finite subtree of an initial segment of T^σ (or T^A for any $A \succ \sigma$) whose height is e ,
- (b) p is a "path" on t of length e ,
- (c) for any odd $i < |\rho|$, if $\rho(i) = \langle t_i, p_i \rangle$, then $t_i \subsetneq t$ and $p_i \subsetneq p$.

VERIFICATION:

(a) T^* is recursive by construction.

(b) We show that there exists a path on T^* . Let P_0 be the unique path of T^0 , and P_1 be the unique path of T^{P_0} . We can define a path P on T^* as follow. Given $\sigma \prec P$ defined, assume that $|\sigma| = 2e$. We define $P(2e) =$ the shortest $\sigma \prec P_0$ such that σ computes a finite subtree $t \subset T^{P_0}$ containing $P_1 \upharpoonright e$ as a cofinal "path". Then we let $P(2e + 1) = \langle t, P_1 \upharpoonright e \rangle$, while t is the smallest such finite subtree.

(b) If P is a path on T^* , then the even part of P is the unique path P_0 of T^0 . For the odd part, by monotonicity, $\bigcup_{i \text{ is odd}} t_i$ is an infinite tree and $\bigcup_{i \text{ is odd}} p_i$ is an infinite path on that tree. Assume to contradiction that $\bigcup_i t_i \not\subseteq T^{P_0}$, then some $t_i \not\subseteq T^{P_0} \upharpoonright \frac{i-1}{2}$. For long enough σ , we can assume $T^{P_0} \upharpoonright \frac{i-1}{2} = T^\sigma \upharpoonright \frac{i-1}{2}$. Therefore no subtree of $T^\sigma \upharpoonright \frac{i-1}{2}$ extends t_i , and so $\langle t_i, p_i \rangle$ won't be on an infinite path. A contradiction. Now, $\bigcup_i t_i$ is an infinite subtree of T^{P_0} and $\bigcup_i p_i$ is a path on it. Since P_1 is the unique path of T^{P_0} , $\bigcup_i p_i = P_1$ as desired.

(c) To compute $0''$ from a path P of T^* . Since $P_1 = \bigcup_i p_i$ computes $0''$, we just look for a large enough $\langle t, p \rangle$ on P and compute with oracle p . □

THIS IS A WRONG PROOF of 4.2.9 (2)! We build a recursive but possibly infinitely branching tree such that it contains exactly one path, which computes $0''$. We hope the path P would satisfies

$$(4.2.9.2) \quad P(e) = t,$$

where t is the last "change point", namely, t is the least such that either for all $s \geq t$, $\Phi_{e,s}^{0'}(e) \downarrow$ and so $\Phi_e^{0'}(e) \downarrow$, or for all $s \geq t$, $\Phi_{e,s}^{0'}(e) \uparrow$ and so $\Phi_e^{0'}(e) \uparrow$.

Note that such a P encodes redundant information just to compute $0''$. To see if $e \in 0''$, just compute up to $\Phi_{e,P(e)}^{0'}(e)$, and see if it converges.

IDEA:

When we are trying to compute every $\Phi_{e,s}^{0'}(e)$, we only allow the tree to grow only upon those recent "change points".

CONSTRUCTION:

Given a $\sigma \in \mathbb{N}^{<\mathbb{N}}$. Let $s = \max(\{|\sigma|\} \cup \text{ran } \sigma)$ be the step we would like to check up to. We define $\sigma \in T$ if and only if for all $e < |\sigma|$, $\sigma(e) = t$, where t is the least such that either for all $t \leq s' \leq s$, $\Phi_{e,s'}^{0'}(e) \downarrow$, or for all $t \leq s' \leq s$, $\Phi_{e,s'}^{0'}(e) \uparrow$.

VERIFICATION:

(a) T is a tree. Given $\tau \in T$ and $\sigma \subset \tau$. For τ , we need to check every point up to, say s^τ steps; for σ , say s^σ steps. Clearly, $s^\sigma \leq s^\tau$, but still no smaller than every $\sigma(e)$. Therefore, every $\sigma(e)$ remains to be the last change point before $s^\sigma \leq s^\tau$, so $\sigma \in T$.

(b) T is recursive by definition.

(c) The path P defined in (4.2.9.2) is a path on T . For any n , we have to check for every $e < n$ if $P(e)$ is the last change point up to some step $s^n \geq P(e)$, but it must be, since there will no change point every . **NO! If finally $\Phi_e^{0'}(e) \uparrow$, it might be the case that $\Phi_{e,s}^{0'}(e)$ converge, diverge,... for infinitely many times. Then there will be no path!**

Here is another WRONG approaching! If we just want to make

$$P(e) = \begin{cases} 0, & \text{if } \Phi_e^{0'}(e) \uparrow, \\ t+1, & \text{if } \Phi_{e,t}^{0'} \downarrow. \end{cases}$$

Then the construction will fail: either the tree is not recursive (or not a tree at all), or there will be a wrong path. **WHY we need to set the starting stage in the right proof?**

Exercise 4.3.17. Show that

- (1) there is a set A such that $A \leq_T 0'$ but $A \not\leq_{wtt} 0'$;
- (2) there are sets A, B such that $A \leq_{wtt} B$ but $A \not\leq_{tt} B$.

Proof. For (1).

We build a set A such that $A \leq_T 0'$, but $A \not\leq_{wtt} 0'$. For each $n = \langle e, i \rangle$, let

$$A_s(n) = \begin{cases} 1, & \text{if } \Phi_{e,s}^{0'}(n) \downarrow = 0 \text{ and } \varphi_{i,s}(n) \downarrow > \text{ use } \Phi_{e,s}^{0'}(n) \\ 0, & \text{otherwise.} \end{cases}$$

VERIFICATION:

(a) Clearly, $\langle A_s \rangle_{s \in \mathbb{N}}$ is recursive.

(b) Fix any $n = \langle e, i \rangle$. If $\Phi_e^{0'}(n) \downarrow$, then both $\Phi_{e,s}^{0'}(n)$ and use $\Phi_{e,s}^{0'}(n)$ converges with respect to $s \rightarrow \infty$, and so $\lim_{s \rightarrow \infty} A_s(n) \downarrow$. Else if $\Phi_e^{0'}(n) \uparrow$. If it is the case that $\Phi_{e,s}^{0'}(n)$ converge at the statue \uparrow (with respect to $s \rightarrow \infty$), then $\lim_{s \rightarrow \infty} A_s(n) \downarrow = 0$. It is also possible that $\Phi_{e,s}^{0'}(n) \downarrow$ for infinitely many times but still $\Phi_e^{0'}(n) \uparrow$. In this case, we must have the negation of $\varphi_{i,s}(n) \downarrow > \text{ use } \Phi_{e,s}^{0'}(n)$ for cofinite many s , and so $\lim_{s \rightarrow \infty} A_s(n) \downarrow = 0$. Therefore, $\lim_{s \rightarrow \infty} A_s(n)$ always converges, and so $A \leq_T 0'$.

(c) Note that the only case when $\lim_{s \rightarrow \infty} A_s(n) \downarrow = 1$ is both $\Phi_e^{0'}(n) \downarrow = 0$ and $\varphi_i(n) \downarrow > \text{ use } \Phi_e^{0'}(n)$. Therefore, A diagonalized every possibility of $A \leq_{wtt} 0'$. \square

Proof. For (2).

This proof uses finite injury priority method.

IDEA: Recall that $A \leq_{tt} B$ if and only if there is a total functional Φ_e (i.e. Φ_e^X is total for any X) such that $A = \Phi_e^B$. We build A and B together to satisfy the requirements

$$R_e : \quad \text{If } \Phi_e^X \text{ is total for all } X, \text{ then } A \neq \Phi_e^B.$$

We also need to code enough information in B so that $A \leq_{wtt} B$.

CONSTRUCTION:

Step 0: Let $A_0 = B_0 = \emptyset$, all requirements R_e are unsatisfied, the boundaries for protecting what we have done for requirements of indices $\leq e$ is set to be $b_{e,0} = 0$ for every e .

Step $s+1$: Assume A_s and B_s are defined. Search for the first $\langle e, \sigma, t \rangle$ such that R_e is currently marked as unsatisfied, σ is a finite 01-string such that

$$(B_s \upharpoonright b_{e,s}) \frown \{1\}^{e+1} \prec \sigma \prec (B_s \upharpoonright b_{e,s}) \frown \{1\}^{e+1} \frown \{0\}^{\mathbb{N}},$$

and

$$\Phi_{e,t}^\sigma(b_{e,s} + e) \downarrow.$$

$x = b_{e,s} + e$ is where we want to diagonalize for R_e .

Note that since there are infinitely many unsatisfied total functional Φ_e , we can always find such $\langle e, \sigma, t \rangle$. Now, assume e and σ are what we find.

Let $b_{i,s+1} = b_{i,s}$ for $i < e$ (we keep the boundaries untouched, since we would not injure efforts for these requirements), and

$$b_{j,s+1} = \max\{\text{use } \Phi_e^\sigma(x), b_{e,s} + e + 2\}$$

for all $j \geq e$ (we set the boundary for satisfied R_e . All R_j for $j > e$ become unsatisfied, so no additional protection needed).

We set $A_{s+1}, B_{s+1} \in 2^{b_{e,s+1}}$ as follow. Let $B_{s+1} \preceq \sigma$. Namely, we attach $e+1$ many 1' after $B_s \upharpoonright b_{e,s}$ and some (at least one) 0's enough to be used as oracle in the computation $\Phi_e^\sigma(x)$. Let $A_{s+1}(x) = 1 - \Phi_e^\sigma(x)$, and $A_{s+1}(y) = 0$ for $y \neq x$ and $y \geq b_{e,s}$.

We mark R_e as satisfied, and R_j *unsatisfied* for all $j > e$.

We define A and B such that $A(x) = \lim_{s \rightarrow \infty} A_s(x)$ and $B(x) = \lim_{s \rightarrow \infty} B_s(x)$.

VERIFICATION:

By the construction, efforts for requirement R_e can only be injured when we act for requirements R_i ($i < e$).¹ Therefore, for each e the efforts for R_e can only be injured finitely many times. Now, fix an e such that Φ_e is a total functional. There is a time, say s , when there will be no more acts for any R_i for $i < e$. The intended diagonalization point $b_{e,s} + e$ is now fixed. Since Φ_e is a total functional, we are guaranteed to find the right σ . Therefore, R_e will eventually be satisfied. Hence, $A \not\leq_{tt} B$.

To see that $A \leq_{wt} B$ witness by the function $x \mapsto x+2$. For each x , to compute $A(x)$, we first look at $B(x)$ and $B(x+1)$. If they are not 10, then $A(x) = 0$. If they are, we count the number of continuous 1's starting from $B(x)$ backward, say it is $e+1$. Then we try to compute $\Phi_e^\sigma(x)$ for some σ extending $B \upharpoonright (x+1)$ only by 0's. Such a σ will be found. By our construction $\Phi_e^B(x) \downarrow$ and the computation uses an initial segment of B of the form of such σ . Then $A(x) = 1 - \Phi_e^\sigma(x) = 1 - \Phi_e^B(x)$. Note that we have only used information from $B \upharpoonright (x+2)$. \square

Exercise 4.5.6. $\text{REC} = \{e \in \mathbb{N} \mid W_e \text{ is recursive}\}$ is 1-complete for Σ_3 class.

Proof. REC is Σ_3 because W_e is recursive if and only if

$$\exists d \forall n [(\forall s \Phi_{e,s}(n) \uparrow \rightarrow \exists t \Phi_{d,t}(n) \downarrow = 0) \wedge (\exists u \Phi_{e,u}(n) \downarrow \rightarrow \exists v \Phi_{d,v}(n) \downarrow = 1)],$$

which is equivalent to

$$\exists d \forall n \forall u \exists s \exists t \exists v [(\Phi_{e,s}(n) \uparrow \rightarrow \Phi_{d,t}(n) \downarrow = 0) \wedge (\Phi_{e,u}(n) \downarrow \rightarrow \Phi_{d,v}(n) \downarrow = 1)].$$

¹We always have $b_{i,s} \leq b_{j,s}$ for any $i < j$ and any s . At the end of each successor step, both $A_{s+1} \upharpoonright b_{e,s} = A_s \upharpoonright b_{e,s}$ and $B_{s+1} \upharpoonright b_{e,s} = B_s \upharpoonright b_{e,s}$, so our act does not injure the efforts for R_i ($i < e$).

The latter one is Σ_3

Now, given any Σ_3 set X . We can assume $X = \{x \mid \exists y R(x, y)\}$ where R is a Π_2 relation. Since $\text{inFIN} = \{e \mid W_e \text{ is infinite}\}$ is 1-complete for Π_2 class, there is a 1-1 recursive function g such that $R(x, y)$ if and only if $W_{g(x, y)}$ is infinite.

We define a 1-1 recursive function $f : \mathbb{N} \rightarrow \mathbb{N}$ so that for each $x \in \mathbb{N}$, $W_{f(x)}$ is an r.e. set generated as follow.

We will try to diagonalize to make $\overline{W_{f(x)}}$ not r.e. That is we hope it will meet the requirements:

$$R_y : \overline{W_{f(x)}} \neq W_y.$$

At step 0, we let $\overline{W_{f(x), 0}} = \mathbb{N}$ and so $W_{f(x), 0} = \emptyset$, the movable marker Γ_y is located at $b_{x, 0}^y = y$ for every y .

At step $s+1$. Assume $\overline{W_{f(x), s}} = \{b_{x, s}^0 < \dots < b_{x, s}^y < \dots\}$, namely the movable marker Γ_y is located at $b_{x, s}^y$ for each y .

For s is even, as before, for each $y \leq s$, if we find $W_{g(x, y), s} \neq W_{g(x, y), s+1}$, we enumerate $b_{x, s}^y$ from $\overline{W_{f(x), s}}$ into $W_{f(x), s+1}$. By doing this, we move the marker Γ_i (for $i \geq y$) from $b_{x, s}^i$ to $b_{x, s+1}^{i+1}$. Note that we only have to act for finitely many $y \leq s$. We can assume we act at most once at each step, say for y , in which case the movable marker Γ_i will not move (namely $b_{x, s+1}^i = b_{x, s}^i$) if $i < y$, or move to $b_{x, s+1}^i = b_{x, s}^{i+1}$ if $i \geq y$. This is how $\overline{W_{f(x), s+1}}$ is defined. If no such y , we do nothing.

For s is odd, we look for $y \leq s$ such that there is (we can assume a unique) $n \in W_{y, s+1} - W_{y, s}$, $n \geq b_{x, s}^y$ and R_y has never been act for. If we found, we enumerate all numbers in $[b_{x, s}^y, n]$ into $W_{f(x), s+1}$, namely, we move the markers Γ_i ($i \geq y$) (finitely rightward) to the location $b_{x, s+1}^i = b_{x, s}^{i+k}$ where k is the least such that $b_{x, s}^{i+k} > n$. If no such y , we do nothing.

Verification.

If $x \in X$, then there exists y such that $W_{g(x, y)}$ is infinite, so $\lim_{s \rightarrow \infty} b_{x, s}^i \uparrow$ for all $i \geq y$, so $\overline{W_{f(x)}} = \{\lim_{s \rightarrow \infty} b_{x, s}^i \mid i \in \mathbb{N}\}$ is finite and $W_{f(x)}$ is cofinite, and so both recursive, and so $f(x) \in \text{REC}$.

If $x \notin X$, i.e. $\forall y W_{g(x, y)}$ is finite and so the marker Γ_y would only be moved rightward finitely many times at odd steps. Since every requirement R_y is act for at most once and a marker Γ_i is only moved rightward at even step when we act for requirements R_y for $y \leq i$. In other word, each Γ_i is moved rightward no more than i times at even steps. Therefore $\lim_{s \rightarrow \infty} b_{x, s}^y \downarrow$ for every y , so $\overline{W_{f(x)}}$ is infinite. Moreover, for every y such that W_y is infinite, R_y must be act for at sometime (since every $b_{x, s}^y$ converges), so that there is $n \in W_y$ but $n \notin \overline{W_{f(x)}}$ witnessing that $\overline{W_{f(x)}} \neq W_y$. Therefore $\overline{W_{f(x)}}$ is not r.e. and $f(x) \notin \text{REC}$ as desired. \square

This is another proof given by Wang Sa.

Proof. As we have shown that $\text{COF} = \{e \in \mathbb{N} \mid W_e \text{ is cofinite}\}$ is 1-complete for Σ_3 class, it suffices to show $\text{REC} \leq_1 \text{COF}$.

By s - m - n Theorem, there is a 1-1 function f such that for each e , $f(e)$ is the index of the following r.e. set:

$$W_{f(e)} = \{\langle i, j \rangle \mid (i \leq j) \wedge (i \in 0' \vee j \in W_e)\}$$

We show that $W_{f(e)}$ is recursive if and only if W_e is cofinite.

Assume W_e is not cofinite. We show $W_{f(e)}$ computes $0'$, and so is not recursive. Let x be any number such that $x \notin 0'$, or we can just assume $0 \notin 0'$. Note that x is a fixed number, which can be built into a program. To see if $i \in 0'$. We wait until finding some $j \in W_e$ such that $j \geq i$ and $j \geq x$, and moreover $\langle x, j \rangle \notin W_{f(e)}$. Such j can always be found, since otherwise either W_e or $0'$ is cofinite. Now, $i \in 0'$ if and only if $\langle i, j \rangle \in W_{f(e)}$.

Now, assume W_e is cofinite. Then there are only finitely many $\langle i, j \rangle$ such that $i \leq j$ and $\langle i, j \rangle \notin W_{f(e)}$. Build this information in the program. To decide if $\langle i, j \rangle \in W_{f(e)}$. First, check if $i \leq j$. If not, return "no"; if so ask the "build in oracle". \square
